User Story 1:
"As a user, I want to be able to input my Steam account and then receive a list of personalized news articles based on my most recently played games."

When the app works:
- User opens our web app
- User logs in/authenticates using their google account
- Web app recommends articles based on their recent games

- To obtain user data, we will use the steam web API
- To generate recommendations, we will use Videogames NEWS rapid API which has a lot of recent news articles stored on it
- We will analyze the user data from the steam API and then use the data from the rapid API to show articles related to the most recently played games

When the app doesn't work:
- User opens our web app
- Logs in using their google account
- Web app is unable to generate articles for some reason, could be due to lack of user data in the steam API or it couldn't find a sufficient match from the rapid API data
- User does not receive article recommendations

    This is important because we want the web app to be able to generate recommendations for each user that has a steam account.
